**865MHz Multiplexing Amplifier**

The ISL59421 is a 865MHz bandwidth multiplexing amplifier designed primarily for video switching. This Mux amp has user-settable gain and also features a high speed three-state function to enable the output of multiple devices to be wired together. All logic inputs have pull-downs to ground and may be left floating. The ENABLE pin, when pulled high, sets the ISL59421 to the low current power-down mode for power sensitive applications - consuming just 5mW.

**TABLE 1. CHANNEL SELECT LOGIC TABLE**

NOTE: Intersil Pb-free plus anneal products employ special Pb-free material sets; molding compounds/die attach materials and 100% matte tin plate termination finish, which are RoHS compliant and compatible with both SnPb and Pb-free soldering operations. Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.

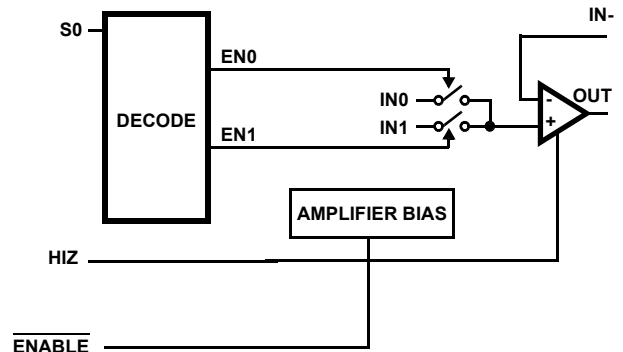

**Features**

- 865MHz (-3dB) Bandwidth ( $A_V = 1, V_{OUT} = 100mV_{P-P}$ )
- 350MHz (-3dB) Bandwidth ( $A_V = 2, V_{OUT} = 2V_{P-P}$ )
- Slew Rate ( $A_V = 1, R_L = 500\Omega, V_{OUT} = 4V$ ) . . . . .1417V/ $\mu$ s
- Slew Rate ( $A_V = 2, R_L = 500\Omega, V_{OUT} = 5V$ ) . . . . .2008V/ $\mu$ s
- Adjustable Gain
- High Speed Three-state Output (HIZ)
- Low Current Power-Down . . . . .5mW
- Pb-Free Plus Anneal Available (RoHS Compliant)

**Applications**

- HDTV/DTV Analog Inputs
- Video Projectors
- Computer Monitors
- Set-top Boxes
- Security Video
- Broadcast Video Equipment

**Functional Diagram**

ENABLE pin must be low in order to activate the HIZ state

**Absolute Maximum Ratings** ( $T_A = 25^\circ\text{C}$ )

Supply Voltage (V+ to V-)	11V	Storage Temperature Range	-65°C to +150°C
Input Voltage	V- -0.5V, V+ +0.5V	Ambient Operating Temperature	-40°C to +85°C
Supply Turn-on Slew Rate	1V/ $\mu\text{s}$	Operating Junction Temperature	-40°C to +125°C
IN- Input Current (Note 1)	5mA	Power Dissipation	See Curves
Digital & Analog Input Current (Note 1)	50mA	$\theta_{JA}$	See Curves
Output Current (Continuous)	50mA		
<b>ESD Rating</b>			
Human Body Model (Per MIL-STD-883 Method 3015.7)	2500V		
Machine Model	300V		

CAUTION: Stresses above those listed in "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress only rating and operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied.

**NOTE:**

1. If an input signal is applied before the supplies are powered up, the input current must be limited to these maximum values.

IMPORTANT NOTE: All parameters having Min/Max specifications are guaranteed. Typical values are for information purposes only. Unless otherwise noted, all tests are at the specified temperature and are pulsed tests, therefore:  $T_J = T_C = T_A$

**Electrical Specifications** V+ = +5V, V- = -5V, GND = 0V,  $T_A = 25^\circ\text{C}$ ,  $R_L = 500\Omega$  to GND unless otherwise specified.

## Application Circuits

FIGURE 25A. GAIN OF 1 APPLICATION CIRCUIT

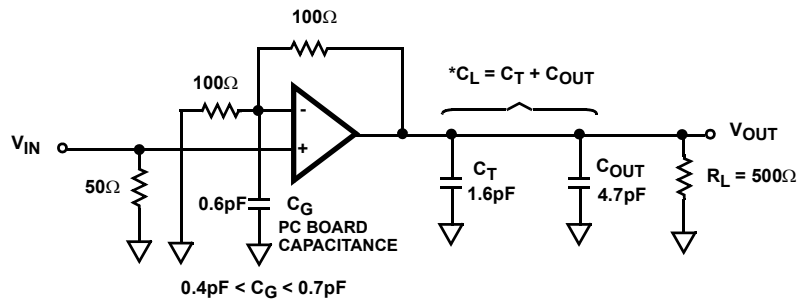

FIGURE 25B. GAIN OF 2 APPLICATION CIRCUIT

## Application Information

### General

The ISL59421 is a 2:1 mux that is ideal as a matrix element in high performance switchers and routers. The ISL59421 is optimized to drive 5pF in parallel with a 500Ω load. The capacitance can be split between the PCB capacitance and an external load capacitance. Its low input capacitance and high input resistance provide excellent 50Ω or 75Ω terminations.

### Parasitic Effects on Frequency Performance

#### Capacitance at the Inverting Input

The AC performance of current-feedback amplifiers in the non-inverting gain configuration is strongly affected by stray capacitance at the inverting input. Stray capacitance from the inverting input pin to the output ( $C_F$ ), and to ground ( $C_G$ ), increase gain peaking and bandwidth. Large values of either capacitance can cause oscillation. The ISL59421 has been optimized for a 0.4pF to 0.7pF capacitance ( $C_G$ ). Capacitance ( $C_F$ ) to the output should be minimized. To achieve optimum performance the feedback network resistor(s) must be placed as close to the device as possible. Trace lengths greater than 1/4 inch combined with resistor pad capacitance can result in inverting input to ground capacitance approaching 1pF. Inverting input and output traces should not run parallel to each other. Small size surface mount resistors (604 or smaller) are recommended.

#### Capacitance at the Output

The output amplifier is optimized for capacitance to ground ( $C_L$ ) directly on the output pin. Increased capacitance causes higher peaking with an increase in bandwidth. The optimum range for most applications is ~1.0pF to ~6pF. The optimum value can be achieved through a combination of PC board trace capacitance ( $C_T$ ) and an external capacitor ( $C_{OUT}$ ). A good method to maintain control over the output pin capacitance is to minimize the trace length ( $C_T$ ) to the next component, and include a discrete surface mount capacitor ( $C_{OUT}$ ) directly at the output pin.

#### Feedback Resistor Values

The AC performance of the output amplifier is optimized with the feedback resistor network ( $R_F$ ,  $R_G$ ) values recommended in the application circuits. The amplifier bandwidth and gain peaking are directly affected by the value(s) of the feedback resistor(s) in unity gain and gain >1 configurations. Transient response performance can be tailored simply by changing these resistor values. Generally, lower values of  $R_F$  and  $R_G$  increase bandwidth and gain peaking. This has the effect of decreasing rise/fall times and increasing overshoot.

#### Ground Connections

For the best isolation and crosstalk rejection, the GND pin and NIC pins must connect to the GND plane.

### Control Signals

S0,  $\overline{\text{ENABLE}}$ , HIZ - These pins are TTL/CMOS compatible control inputs. The S0 pin selects which one of the inputs connect to the output. The  $\overline{\text{ENABLE}}$ , HIZ pins are used to disable the part to save power and three-state the output amplifiers, respectively. For control signal rise and fall times less than 10ns the use of termination resistors close to the part will minimize transients coupled to the output.

### Power-Up Considerations

The ESD protection circuits use internal diodes from all pins the V+ and V- supplies. In addition, a dV/dT-triggered clamp is connected between the V+ and V- pins, as shown in the Equivalent Circuits 1 through 4 section of the Pin Description table. The dV/dT triggered clamp imposes a maximum supply turn-on slew rate of  $1\text{V}/\mu\text{s}$ . Damaging currents can flow for power supply rates-of-rise in excess of  $1\text{V}/\mu\text{s}$ , such as during hot plugging. Under these conditions, additional methods should be employed to ensure the rate of rise is not exceeded.

Consideration must be given to the order in which power is applied to the V+ and V- pins, as well as analog and logic input pins. Schottky diodes (Motorola MBR0550T or equivalent) connected from V+ to ground and V- to ground (Figure 26) will shunt damaging currents away from the internal V+ and V- ESD diodes in the event that the V+ supply is applied to the device before the V- supply.

If positive voltages are applied to the logic or analog video input pins before V+ is applied, current will flow through the internal ESD diodes to the V+ pin. The presence of large decoupling capacitors and the loading effect of other circuits connected to V+, can result in damaging currents through the ESD diodes and other active circuits within the device. Therefore, adequate current limiting on the digital and

analog inputs is needed to prevent damage during the time the voltages on these inputs are more positive than V+.

### HIZ State

An internal pull-down resistor connected to the HIZ pin ensures the device will be active with no connection to the HIZ pin. The HIZ state is established within approximately 30ns (Figure 18) by placing a logic high ( $>2\text{V}$ ) on the HIZ pin. If the HIZ state is selected, the output is a high impedance  $1.4\text{M}\Omega$ . Use this state to control the logic when more than one mux shares a common output.

In the HIZ state the output is three-stated, and maintains its high Z even in the presence of high slew rates. The supply current during this state is basically the same as the active state.

### $\overline{\text{ENABLE}}$ & Power Down States

The enable pin is active low. An internal pull-down resistor ensures the device will be active with no connection to the  $\overline{\text{ENABLE}}$  pin. The Power Down state is established when a logic high ( $>2\text{V}$ ) is placed on the  $\overline{\text{ENABLE}}$  pin. In the Power Down state, the output has no leakage but has a large capacitance (on the order of 15pF), and is capable of being back-driven. Under this condition, large incoming slew rates can cause fault currents of tens of mA. **Do not use this state as a high Z state for applications driving more than one mux on a common output.**

### Limiting the Output Current

No output short circuit current limit exists on this part. All applications need to limit the output current to less than 50mA. Adequate thermal heat sinking of the parts is also required.

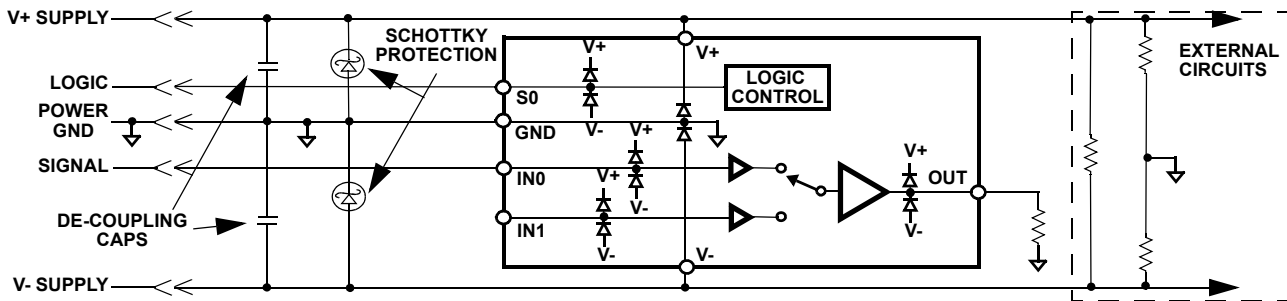

FIGURE 26. SCHOTTKY PROTECTION CIRCUIT

## ***PC Board Layout***

The frequency response of this circuit depends greatly on the care taken in designing the PC board. The following are recommendations to achieve optimum high frequency performance from your PC board.

- The use of low inductance components such as chip resistors and chip capacitors is strongly recommended.
- Minimize signal trace lengths. Trace inductance and capacitance can easily limit circuit performance. Avoid sharp corners, use rounded corners when possible. Vias in the signal lines add inductance at high frequency and should be avoided. PCB traces greater than 1" begin to exhibit transmission line characteristics with signal rise/fall times of 1ns or less. High frequency performance may be degraded for traces greater than one inch, unless strip lines are used.
- Match channel-channel analog I/O trace lengths and layout symmetry. This will minimize propagation delay mismatches.
- Maximize use of AC de-coupled PCB layers. All signal I/O lines should be routed over continuous ground planes (i.e. no split planes or PCB gaps under these lines). Avoid vias in the signal I/O lines.
- Use proper value and location of termination resistors. Termination resistors should be as close to the device as possible.
- When testing use good quality connectors and cables, matching cable types and keeping cable lengths to a minimum.
- Minimum of 2 power supply de-coupling capacitors are recommended (1000pF, 0.01 $\mu$ F) as close to the device as possible. Avoid vias between the cap and the device because vias add unwanted inductance. Larger caps can be farther away. When vias are required in a layout, they should be routed as far away from the device as possible.
